Northeastern Pacific Albacore Survey Part 1. Biological Observations

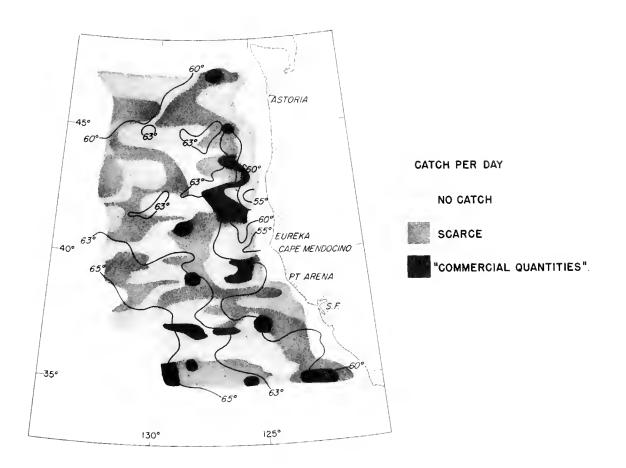

Explanatory Note

The series embodies results of investigations, usually of restricted scope, intended to aid or direct management or utilization practices and as guides for administrative or legislative action. It is issued in limited quantities for the official use of Federal, State or cooperating Agencies and in processed form for economy and to avoid delay in publication.

Special Scientific Report--Fisheries No. 310

WASHINGTON: JULY 1959

ABSTRACT

This report lists the biological data collected aboard research vessels Hugh M. Smith and John R. Manning and nine chartered commercial vessels during the Northeastern Pacific Albacore Survey (NEPAS). The survey was developed to map the distribution of albacore in the northern area of the United States west coast albacore fishery during the summer of 1957.

Bureau of Commercial Fisheries
Biological Laboratory 1/
Honolulu, Hawaii

Albacore tuna, Germo alalunga (Bonnaterre) were landed commercially in ports of Washington and Oregon for the first time in 1937. During 1939 they began to appear in exploratory catches of commercial vessels off British Columbia, Canada. By 1945 the annual commercial catch exceeded a million pounds. Large catches were consistently made off British Columbia by 1948 with good fishing extending as far north as Queen Charlotte Islands (Powell et al. 1952), which represented the farthest northward extension of the fishery. Following 1948 the fishery declined rapidly; by 1951 only a few albacore were taken commercially north of California.

The return of albacore to these northern waters was indicated in 1955 when scattered fish were reported from the area by research vessels of the University of Washington and of the United States Fish and Wildlife Service (Graham 1957, Holmberg 1955). In 1956, vessels from these agencies again reported fish in the area and commercial vessels, which followed up these reports, developed a small albacore fishery off Oregon (Anonymous 1956, Frolander and Lincoln 1956).

The Northeastern Pacific Albacore Survey or NEPAS was designed to map the distribution of albacore in this northern area and to determine how the distribution was related to oceanographic and biological phenomena. The survey was conducted by the Biological Laboratory of the Bureau of Commercial Fisheries at Honolulu, Hawaii, as a part of their Saltonstall-Kennedy (68 Stat. 376) albacore tuna project, and in cooperation with members of the fishing industry, and the fishery research agencies of California, Oregon, and Washington. The Pacific Marine Fisheries Commission acted as liaison for the cooperating agencies.

The survey area extended from $35^{\circ}N$, to $47^{\circ}N$, latitude and from 50 to 350 miles offshore. The southern limit of the survey area was just

north of Point Arguello, California, which approximates the northern summer limit of the southern California albacore fishery. northern limit approached generally the northernmost penetration of the west coast albacore fishery during the summer. Inshore and offshore limits were determined from data gathered on previous cruises which indicated that a definite scarcity of fish existed beyond these boundaries during the summer (Graham 1957, Anonymous 1957). Thus, the survey was placed off the coasts of northern California, Oregon, and Washington. The period covered was from July 22 to August 1 (1957), a time when the west coast albacore fishery could be expected to reach or approach its peak in production (Clemens 1955).

Nine charter vessels were assigned to the trolling tracks shown in figure 1. Six of the vessels carried scientific observers provided by California Fish and Game (2), Oregon Fish Commission (1), Washington State Department of Fisheries (1), and Honolulu Biological Laboratory (2). The vessels, operators, home ports, and names and agencies of the observers are given in table 1. The charter vessels were augmented by the two Honolulu Laboratory vessels, the Hugh M. Smith and the John R. Manning, which operated in the survey area making oceanographic and biological observations.

This report lists the biological data collected during the survey. They are presented here to make them readily available to other agencies studying the ecology of the albacore in the eastern Pacific. Descriptive and analytical publications will follow. Oceanographic and plankton data will also be the subjects of separate reports.

The John R. Manning departed on cruise 36 from Honolulu on June 14, 1957, to make a preliminary troll and gill-net survey of the area. The Manning travelled northeast to 42°N., 135°W. (see fig. 2), returned south to 31°N., and then zigzagged northward through the NEPAS area. The Manning arrived in Astoria, Oregon, on July 16 and remained there until the start of NEPAS on July 22. Subsequently, she proceeded

^{1/} Formerly the Pacific Oceanic Fishery Investigations.

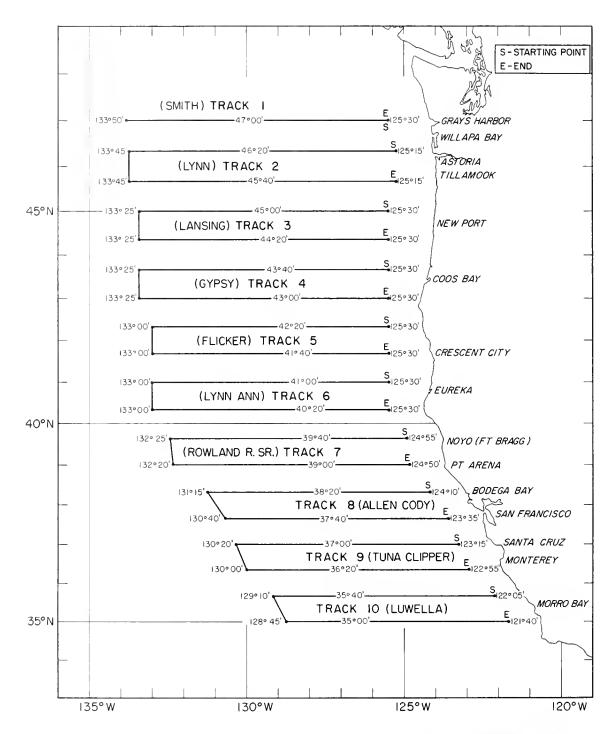

Figure 1. -- Proposed trolling tracks for NEPAS and the names of the vessels assigned.

south through the NEPAS area, transferring equipment to the charter vessels, and then crossed into and out of the coastal band of cold water, and checked areas where the charter vessels reported good catches. The Manning returned to Honolulu August 20, 1957.

The <u>Hugh M. Smith</u> departed from Honolulu on cruise 40 on July 1, 1957, to run a line of oceanographic stations between Oahu and 38°35'N., 143°28'W. (see fig. 3). The <u>Smith</u> then conducted an oceanographic and trolling survey between 40°N. and 46°N. and arrived

1/ Except where operators are indicated, vessels were operated by the owners.

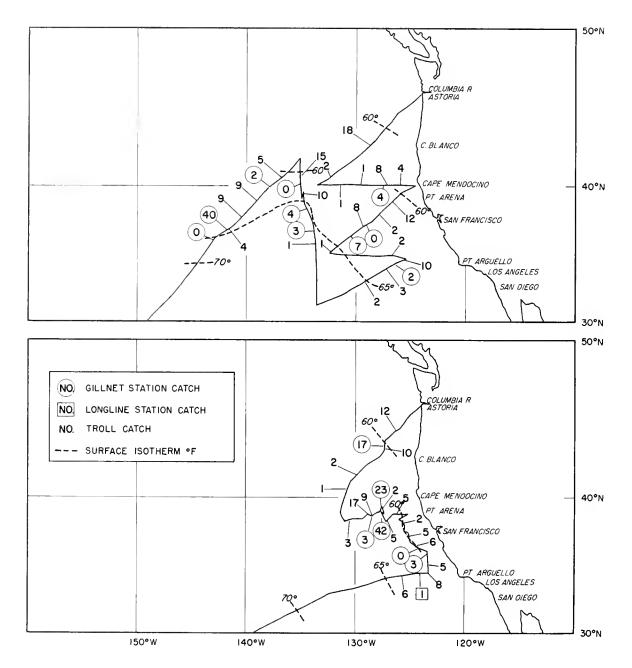

Figure 2. --Albacore tuna catches made with trolling gear, gill nets, and longline by the <u>John R. Manning</u> (cruise 36) during the Northeastern Pacific Albacore Survey. Upper panel shows catches on track outbound from Honolulu and lower panel shows catches on track outbound from Astoria, Oregon.

in Astoria, Oregon, on July 18. During the period July 22 to August 15, the Smith acted as coordinating vessel for the NEPAS survey, completed the northernmost trolling track of NEPAS, conducted an oceanographic and trolling survey of the NEPAS area, and adjusted her track to cover areas which had been assigned to vessels forced to withdraw from

the survey. After a stop for repairs at Oakland, California, from August 15-26, 1957, the Smith completed the oceanographic and trolling survey of the NEPAS area and departed for Honolulu on August 29, again occupying a line of oceanographic stations en route. She returned to Honolulu on September 5, 1957.

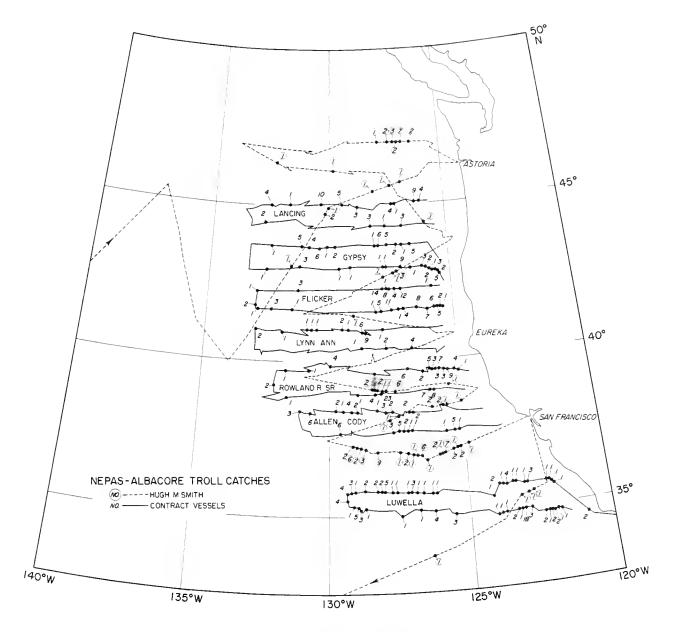

Figure 3. -- Albacore tuna catches by the Hugh M. Smith and the charter vessels during the Northeastern Pacific Albacore Survey.

Eight of the charter vessels started the NEPAS survey on schedule on July 22, 1957; the ninth started on July 23. All vessels completed the survey of their assigned tracks on either July 31 or August 1 except the Tuna Clipper and the Lynn. The fresh-water supply of the Lynn became contaminated with salt water and she was forced to withdraw from the survey about 150 miles from her starting point. The Tuna Clipper encountered heavy weather at the start of the survey and was forced to return to port in a leaking condition after completing 30 miles of her track. Several of the

other vessels sustained storm damage (e. g., the Luwella broke both trolling booms and her radio antenna), but they were able to make repairs en route and complete their tracks.

RESULTS OF FISHING

Trolling

Charter vessels trolled 6 to 12 lines at speeds generally varying from 5 to 7 knots. Daylight trolling along the tracks was continuous; the vessels drifted at night. The Smith

trolled 5 lines and the Manning 6 to 9 lines at speeds of 5 to 7 knots when in the survey area. A variety of jigs and feathered lures was used by all vessels. The troll catches of albacore are presented in tables 2, 3, and 4 and figures 2 and 3. Catch positions were not available for the charter vessel Lynn.

Albacore taken in viable condition on the troll lines were tagged and released. Charter vessels employed the California type G tag

(Wilson 1953); Smith and Manning alternated the use of this tag with a new dart tag (Yamashita and Waldron 1958). The tagging results from each vessel are summarized in table 5. To date, 5 recoveries have been made (Otsu MS)²/₂.

2/ Otsu, T. MS. Albacore migration and growth in the North Pacific Ocean as estimated from tag recoveries. Biological Laboratory, Honolulu.

Gill-net Fishing

Eighteen shackles of gill nets with meshes varying from $4 \ 1/2$ to $7 \ 1/2$ inches, stretched measure, were fished by the Manning. An individual set consisted of a $7 \ 1/2$ -inch mesh shackle placed at each end of the set and adjoin-

ing one of these was a 4 1/2-inch mesh shackle; and eight 5 1/2-inch mesh and seven 6 1/2-inch mesh shackles were alternated in the center of the set. Construction details of the nets are given by Graham and Mann $(MS)^{3/2}$.

Sets were usually made at dusk and retrieved at dawn. One 24-hour station was completed in an area of abundance off Point Arena immediately following an overnight set in which 42 albacore were captured (fig. 2). The 18-shackle set was halved for this operation and five baskets of longline, described below, were attached to an end of each half. Four 6-hour consecutive sets were made, alternating the two halves, between the hours of 1500 on July 30 and 1531 on July 31.

Gill-net catches made during the cruise are given in tables 6 and 7; the lengths of the albacore caught are listed in table 8. A list of the common names of fishes appearing in these tables and other portions of this report is presented in table 9 along with the corresponding scientific names.

Longline Fishing

Five baskets of longline were fished with each set of gill nets by attaching them to an end of the set. The longline was similar to that used previously to fish albacore in this area (Mann 1955). The basic unit or basket consisted of 210 fathoms of mainline to which floats were attached at either end. Three-fathom droppers with 1 1/2-fathom leaders were suspended from the mainline at 15-fathom intervals so that there were 13 hooks to a basket. This basic gear was modified to fish at varying depths by changing the depth of the floatline and placing an extra buoy at the center of the basket (omitting the hook at that position). The five baskets were arranged in the following order, starting at the attached end: Two had 3 buoys (one in the center) and no floatlines; two had 2 buoys and no floatlines; and the fifth had 2 buoys and 2-fathom floatlines. A sound ing tube (Graham 1957) was placed on each basket of gear; and these showed that during the cruise the minimum fishing depth was about 25 feet and the maximum about 430 feet. No albacore were taken on this gear (tables 6 and 7).

A single albacore (68.6 cm. in fork length) was captured on a special set of longline which replaced a scheduled gill-net station cancelled because of a winch breakdown. Five baskets, each equipped with 3 buoys (one in the center) and no floatlines, were fished. This special set was made immediately following a catch of fish on trolling lines and extended from 1345 through 1800 hours (fig. 2). The hooks were baited with small herring (<6 inches), in contrast to the five baskets attached to gill nets on which large herring (>6 inches) were used.

STOMACH ANALYSES

One hundred and ninety-five albacore stomachs were examined in the field and 43 stomachs, believed to contain food, were preserved for laboratory analysis. In the field study, food items were divided into the following major groups: Squid, saury, other fish, shrimp-like plankton, and copeped and amphipod-like plankton. Food items of the first three groups were rated as to size by considering total lengths less than 5 inches as small, 5 through 10 inches as medium, and greater than 10 inches as large. The displacement volume (≥ 5 ml.) of the contents of each stomach was determined and any unidentifiable remains

noted. The data obtained with both types of gear, troll and gill net, are presented in table 10.

HOLDING EXPERIMENTS

The rectangular port brine tank, 8 1/2 feet deep and 6 1/2 feet wide fore and aft, of the John R. Manning was used to hold troll-caught albacore which were landed alive and in good condition. Water entering the tank flowed diagonally across the upper portion of the tank and then returned along its sides and bottom. Water was removed from the bottom diagonally across from the inflow. The volume of flow was such that the contents of the 2, 150-gallon tank were replaced approximately every 35 minutes. Fourteen albacore, ranging from 54 cm. to 68 cm. in fork length, were held in the tank for periods varying from a few minutes to 14 hours (table 11).

NIGHT-LIGHT OBSERVATIONS

Observations of organisms under lights were made from the Smith (table 12), the Manning (table 13), and two charter vessels (table 14) while they were drifting at night. The Smith made her observations under deck lights, which remained on all night, by estimating every 2 hours the number and size of sauries present. The Manning turned on the deck lights for 1 hour during darkness and estimated the number, and usually the size, of sauries and squids which were attracted. The charter vessel Flicker made observations between 2130 and 2200 hours each night using a single sealedbeam light. Twenty or fewer sauries, when seen at one instant during the period of observation, were classed as few, 21 to 50 as moderate, and 51 or more as abundant. Rowland R. Sr. made her observations at 2200 and the amount of bait or forage and the amount of luminescence were recorded in relative terms.

SIGHTINGS OF FISH, BIRDS, AQUATIC MAMMALS

The wheel watches of the Smith and Manning maintained logs of fish, birds, and aquatic mammals sighted during the daylight hours. These observations are tabulated in tables 15 and 16. The charter vessels also maintained a rough log of such sightings which are tabulated in table 17.
